Hypothesis Tests for the Mean

- Same process as before but we need to be careful about our test-statistic.
- Let X_1, \ldots, X_n be i.i.d random variables with (unknown) mean μ and (unknown) variance σ^2 .
- ▶ Set H_0 : $\mu = \mu_0$ and H_1 for some number μ_0 and choose α .
- Determine test-statistic...
 - We know under the null, $\overline{X} \sim N(\mu_0, \frac{\sigma^2}{n})$ for large n.
 - ▶ But we don't know σ^2 ! Calculate s^2 (the sample variance).
 - Standardize:

$$T = rac{\overline{X} - \mu_0}{s/\sqrt{n}}$$

▶ It turns out T is not normally distributed so can not use z-chart! It is t-distributed with n-1 "degrees of freedom".

The *t*-distribution

- Similar to the normal distribution, but with heavier tails.
- ▶ This is to account for the uncertainty in not knowing σ^2 .
- As n gets bigger, the estimate s^2 is better and the t-distribution gets closer to the normal distribution. When $n = \infty$, the t-distribution becomes the normal distribution.
- ▶ This is why we need the "degrees of freedom".

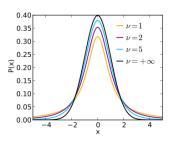

Figure: Credit: Wikipedia. ν is degrees of freedom.

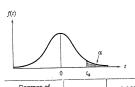

▶ A chocolate block is advertised as being 8 oz. Suppose we are concerned that the chocolate manufacturers are giving us less than 8 oz of chocolate in a block. We collect 15 blocks of chocolate and calculate:

$$\bar{x} = 7.88, \quad s^2 = 0.06.$$

- Step 1 $H_0: \mu = 8$ vs. $H_1: \mu < 8$.
- Step 2 Choose $\alpha = 0.05$.
- Step 3 Test-statistic is

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{7.88 - 8}{\sqrt{0.06/15}} = -1.90$$

Step 4 Find the critical region.

The numbers in the chart below give the critical values (= critical points) for a one-sided up t test. These values depend on the degrees of freedom (left-hand column) and the chosen value α (numerical value of the Type I Error). For example, if there are 24 degrees of freedom and α = 0.05, the critical value is 1.711.

Some manipulation is needed for one-sided down and two-sided tests.

		7	1	1	[[1
Degrees of Freedom	$\alpha = 0.10$	$\alpha = 0.050$	$\alpha = 0.025$	$\alpha = 0.010$	α = 0.005	α = 0001	α = 0.00005

Here, the degrees of freedom is n-1=14. $P(t_{14}>1.761)=0.05$ so $P(t_{14}<-1.761)=0.05$ is the critical region.

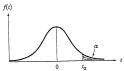

▶ A chocolate block is advertised as being 8 oz. Suppose we are concerned that the chocolate manufacturers are giving us less than 8 oz of chocolate in a block. We collect 15 blocks of chocolate and calculate:

$$\bar{x} = 7.88, \quad s^2 = 0.06.$$

- Step 1 H_0 : $\mu = 8$ vs. H_1 : $\mu < 8$.
- Step 2 Choose $\alpha = 0.05$.
- Step 3 Test-statistic is

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{7.88 - 8}{\sqrt{0.06/15}} = -1.90$$

- Step 4 Find the critical region $\Rightarrow t_{14} < -1.761$
- Step 5 Since t = -1.90 is in the critical region, we reject H_0 .

The numbers in the chart below give the critical values (= critical points) for a one-sided up t test. These values depend on the degrees of freedom (left-hand column) and the chosen value α (numerical value of the Type I Error). For example, if there are 24 degrees of freedom and α = 0.05, the critical value is 1.711.

Some manipulation is needed for one-sided down and two-sided tests.

- ▶ For one-sided tests the critical region is: $t < -t_{n-1,\alpha}$ or $t > t_{n-1,\alpha}$ depending on the direction.
- ▶ For two-sided tests, the critical region is: $t < -t_{n-1,\alpha/2}$ and $t > t_{n-1,\alpha/2}$.
